

## Midterm 2 Study Problem answers

(20pts)

1. Factor each of the following polynomials into linear terms with integer coefficients:

$$h(x) = x^4 - x^3 - 7x^2 + x + 6$$

$$g(x) = x^3 - 3x^2 + 4$$

By using the rational roots theorem and base-x long division, you should be able to determine that:

$$h(x) = (x - 1)(x + 1)(x + 2)(x - 3)$$

and

$$g(x) = (x + 1)(x - 2)^2$$

(25pts)

2.  $f(x) = (x - 1)(x + 1)(x + 2)(x - 3)/(x + 1)(x - 2)(x - 2)$

- i) The  $x+1$  terms cancel, so we have a hole at the point  $(-1, f(-1))$ .
- ii) The roots, where the graph crosses the  $x$ -axis, are at  $x=1$ ,  $-2$  and  $3$ .  
(in orange on graph)
- iii) The vertical asymptote is the line  $x=2$ . (in blue)
- iv) The  $y$ -intercept is at  $(0,1.5)$  (in orange)
- v) Since the degree of  $h(x)$  is one greater than  $g(x)$ , we have a slant asymptote. Since the degree is not equal, or the degree of  $g(x)$  is not greater than the degree of  $h(x)$ , we do not have horizontal asymptotes. (you might on the test, be sure you know how to find them!).
- vi) To find the slant asymptote, use base- $x$  to divide the ORIGINAL  $g(x)$  into  $h(x)$  and throw away the remainder. If you do you should get the slant equation:  $y=x+2$ . Now we should check to see if the graph crosses the slant eq. (you should also do this for horizontal asymptotes!)

You can use the equations with the  $x+1$  term canceled. By cross multiplying you end up with:

$$x^3 - 2x^2 - 5x + 6 = x^3 - 2x^2 - 4x + 8$$

Which has a lot of cancelling, and simplifies quickly to  $x=-2$ . This means the graph crosses the slant equation there, before heading off asymptotically towards the line as  $x$  goes to negative infinity. This point is in yellow on graph.

## Midterm 2 Study Problem answers

By using sign analysis, plugging in particular points, the graph can be sketched easily as:

The hardest part is to compare  $y=x+2$  to other points plugged in. if you plug in say  $-4$ , you will find the function is higher than plugging in to the slant equation so you know that when it crosses the slant, it is higher above it, but as  $x$  goes to  $-\infty$ , it will tend towards it.

(15pts)

3. Using your own derivation of Pascal's triangle, determine the following for the binomial expansion of:

$$\left(-\frac{x^3}{2} - \frac{4}{x^7}\right)^{10}$$

- a. The middle term.

$$(252) \left(-\frac{x^3}{2}\right)^5 \left(-\frac{4}{x^7}\right)^5 = \frac{8064}{x^{20}}$$

- b. The 7<sup>th</sup> term.

$$(210) \left(-\frac{x^3}{2}\right)^4 \left(-\frac{4}{x^7}\right)^6 = \frac{53760}{x^{30}}$$

- c. The coefficient of the term with no  $x$ .

Given  $\left(-\frac{x^3}{2}\right)^a \left(-\frac{4}{x^7}\right)^b$  one can find the equations:  $a + b = 10$  and  $3a = 7b$  which means that  $3a - 7b = 0$ . Solving this system of two equations finds that:

$$a = 7 \text{ and } b = 3.$$

$$(120) \left(-\frac{x^3}{2}\right)^7 \left(-\frac{4}{x^7}\right)^3 = 60 \blacksquare$$

## Midterm 2 Study Problem answers

(20pts)

4. Find a polynomial with integer coefficients that has  $1 + \sqrt[3]{2}$  and  $1 + 2i$  as roots.

First find polynomial with  $1 + \sqrt[3]{2}$  as a root. Let  $x = 1 + \sqrt[3]{2}$  so:

$x - 1 = \sqrt[3]{2}$ . Now cube both sides to get:

$x^3 - 3x^2 + 3x - 1 = 2$ . Then our first polynomial that we could use is:

$$f(x) = x^3 - 3x^2 + 3x - 3$$

Now, like in the previous material, find a polynomial having  $1 + 2i$

As a root. Since we want integer coefficients, we must realize that  $1 - 2i$  is also a root.

So:  $(x - (1 + 2i))(x - (1 - 2i)) = (x - 1 - 2i)(x - 1 + 2i) = x^2 - 2x + 5$

Now just use base-x to multiply the two polynomials you found, together to get:

$x^5 - 5x^4 + 14x^3 - 24x^2 + 21x - 15$  as an answer. Multiplying this by anything non-zero, even involving x, would still be an answer. ■

(5pts)

5. Solve the following radical equation:

$$x - 3 = \sqrt{30 - 2x}$$

Squaring both sides gives:

$$x^2 - 6x + 9 = 30 - 2x$$

Setting everything to zero gives:

$$x^2 - 4x - 21 = 0 = (x - 7)(x + 3)$$

Now plugging in 7 or -3 we find that -3 gives the result that  $-6=6$ , which is false, so 7 is the only solution. Remember that  $\sqrt{36} \neq \pm 6$ . Don't confuse this with solving the EQUATION  $x^2 = 36$  which has the solutions  $\pm 6$ ! ■

(5pts)

6. Solve the equation:  $3(2^{x+4}) = 350$ , rounding the answer to three decimal places.

Divide both sides by 3 to get:

$$2^{x+4} = 116.667$$

Now take the log base 2 of both sides, remembering you need the change of base formula:

$$\log_2(2^{x+4}) = \log_2(116.667) = \frac{\log(116.667)}{\log 2} = 6.866 = x + 4$$

$$x = 6.866 - 4 = 2.866 \blacksquare$$

(5pts)

7. Given  $\ln 2 = 0.693$  and  $\ln 4 = 1.386$ , then find the following ONLY using properties of logarithms and basic arithmetic (you must show your work!)

a.  $\ln 8 = \ln(2 \cdot 4) = \ln 2 + \ln 4 = .693 + 1.386 = 2.079$

b.  $\ln \sqrt{2} = \ln 2^{1/2} = \frac{1}{2} \ln 2 = (.5)(.693) = .3465$

c.  $\ln \frac{1}{64} = \ln 4^{-3} = (-3) \ln 4 = (-3)(1.386) = -4.158 \blacksquare$

(5pts)

8. Write as a single simplified term without logarithms:

$$10^{6 \log xy + \log y - 3 \log x}$$

$$= 10^{\log(xy)^6 + \log y - \log x^3} = 10^{\log \frac{x^6 y^6 y}{x^3}} = 10^{\log x^3 y^7} = x^3 y^7$$
